INDICATIONS AND CLINICAL USE

ORKAMBI (lumacaftor/ivacaftor) is indicated for the treatment of cystic fibrosis (CF) in patients 2 years of age and older who are homozygous for the F508del mutation in the cystic fibrosis transmembrane conductance regulator (CFTR) gene.

Limitations of Use
The efficacy and safety of ORKAMBI have not been established in patients with CF other than those homozygous for the F508del mutation.
Geriatrics (≥65 years of age)
The safety and efficacy of ORKAMBI in patients age 65 years and older have not been evaluated.

Pediatrics (<2 years of age)
The safety and efficacy of ORKAMBI in patients younger than 2 years of age have not been evaluated.

CONTRAINDICATIONS

Patients who are hypersensitive to the active substances within this drug or to any ingredient in the formulation or component of the container. For a complete listing, see DOSAGE FORMS, COMPOSITION AND PACKAGING.

WARNINGS AND PRECAUTIONS

Cardiovascular
Effect on Blood Pressure and Heart Rate
Increased blood pressure and decreased heart rate have been observed during treatment with ORKAMBI (see ADVERSE REACTIONS, ACTION AND CLINICAL PHARMACOLOGY). Blood pressure should be monitored periodically in all patients during treatment. Caution should be observed in patients with pre-existing hypertension, a low heart rate at baseline (<60 beats per minute), or other conditions that might be exacerbated by these hemodynamic effects. Concomitant medications that result in an increase in blood pressure and/or a decrease in heart rate should be avoided to the extent possible during treatment with ORKAMBI.

Hepatic/Biliary/Pancreatic
Hepatic Impairment
Abnormalities in liver function, including advanced liver disease, can be present in patients with CF. Worsening of liver function, including hepatic encephalopathy, in patients with advanced liver disease has been reported in some patients with CF while receiving ORKAMBI. Liver function decompensation, including liver failure leading to death, has been reported in patients with CF who have pre-existing cirrhosis with portal hypertension receiving ORKAMBI.

Use ORKAMBI with caution, monitoring closely after the initiation of treatment, in patients with advanced liver disease (e.g., cirrhosis and/or portal hypertension) and only if the benefits are expected to outweigh the risks (see ADVERSE REACTIONS and ACTION AND CLINICAL PHARMACOLOGY).

If ORKAMBI is used in patients with moderate to severe hepatic impairment, they should be closely monitored after the initiation of treatment and the dose should be reduced as recommended (see DOSAGE AND ADMINISTRATION).
Effect on Liver Function Tests
Serious adverse reactions related to elevated transaminases (alanine transaminase [ALT] or aspartate transaminase [AST]) have been reported in patients with CF receiving ORKAMBI. In some instances, these elevations have been associated with concomitant elevations in total serum bilirubin (see WARNINGS AND PRECAUTIONS, Monitoring and Laboratory Tests).

Dosing should be interrupted and laboratory tests closely followed in patients with ALT or AST greater than 5 x upper limit of normal (ULN) when not associated with elevated bilirubin. Dosing should also be interrupted and laboratory tests closely followed in patients with ALT or AST elevations greater than 3 x ULN when associated with bilirubin elevations greater than 2 x ULN. Following resolution of transaminase elevations, consider the benefits and risks of resuming dosing.

Interactions

Concomitant Use with CYP3A substrates
Lumacaftor is a strong inducer of CYP3A. Co-administration of ORKAMBI with sensitive CYP3A substrates or CYP3A substrates with a narrow therapeutic index is not recommended.

ORKAMBI may substantially decrease hormonal contraceptive exposure, reducing effectiveness. Hormonal contraceptives, including oral, injectable, transdermal, and implantable, should not be relied upon as an effective method of contraception when co-administered with ORKAMBI (see DRUG INTERACTIONS and DOSAGE AND ADMINISTRATION).

Concomitant Use with CYP3A Inhibitors or Inducers
Ivacaftor is a substrate of CYP3A. Medicinal products that inhibit or induce CYP3A activity, may impact the pharmacokinetics of ivacaftor.

The dose of ORKAMBI may need to be adjusted when concomitantly used with strong or moderate CYP3A inhibitors (see DRUG INTERACTIONS and DOSAGE AND ADMINISTRATION).

Exposure to ivacaftor may be reduced by the concomitant use of CYP3A inducers, potentially resulting in loss of ORKAMBI efficacy (see DRUG INTERACTIONS, Drug-Drug Interactions, and Drug-Herb Interactions).

Ophthalmologic
Cataracts
Cases of non-congenital lens opacities without impact on vision have been reported in pediatric patients treated with ORKAMBI and ivacaftor monotherapy. Although other risk factors were present in some cases (such as corticosteroid use and exposure to radiation), a possible risk attributable to ivacaftor cannot be excluded (see TOXICOLOGY). Baseline and follow-up ophthalmological examinations are recommended in pediatric patients initiating ORKAMBI treatment.

Peri-Operative Considerations
Patients after Organ Transplantation
ORKAMBI has not been studied in patients with CF who have undergone organ transplantation. Therefore, use in transplanted patients is not recommended. See DRUG INTERACTIONS for interactions with immunosuppressants such as cyclosporine or tacrolimus.

Renal
Caution is recommended while using ORKAMBI in patients with severe renal impairment (creatinine clearance less than or equal to 30 mL/min) or end-stage renal disease (see DOSAGE AND ADMINISTRATION and ACTION AND CLINICAL PHARMACOLOGY).

Respiratory
Respiratory events (e.g., chest discomfort, dyspnea, and respiration abnormal) were observed more commonly in patients during initiation of ORKAMBI compared to those who received placebo. These events have led to drug discontinuation and can be serious, particularly in patients with percent predicted FEV1 (ppFEV1) <40. Clinical experience in patients with ppFEV1 <40 is limited, and additional monitoring of these patients is recommended during initiation of therapy (see ADVERSE REACTIONS).

Special Populations
Pregnant Women
No adequate and well-controlled studies of ORKAMBI have been conducted in pregnant women. The extent of exposure to ORKAMBI in pregnant women during clinical trials was very limited.

Animal reproduction studies were performed with the individual components of ORKAMBI, lumacaftor and ivacaftor (see TOXICOLOGY). Because animal reproduction studies are not always predictive of human response, ORKAMBI should be used during pregnancy only if the expected benefit to the patient clearly outweighs the potential risk to the fetus.

Lumacaftor
Lumacaftor was not teratogenic in rats and rabbits (see TOXICOLOGY for details). Placental transfer of lumacaftor was observed in pregnant rats and rabbits.

Ivacaftor
Ivacaftor was not teratogenic in rats and rabbits; placental transfer of ivacaftor was observed in pregnant rats and rabbits (see TOXICOLOGY for details).

Ivacaftor impaired fertility and reproductive performance indices in male and female rats at 200 mg/kg/day (approximately 11 and 7 times, respectively, the maximum recommended human dose (MRHD) of the ivacaftor component of ORKAMBI) when dams were dosed prior to and during early pregnancy. No effects on male or female fertility and reproductive performance indices were observed at ≤100 mg/kg/day (approximately 8 and 4.5 times the MRHD of the ivacaftor component of ORKAMBI) (see TOXICOLOGY).

Nursing Women
Both lumacaftor and ivacaftor are excreted into the milk of lactating female rats. Excretion of lumacaftor or ivacaftor into human milk is probable. There are no human trials that have
investigated the effects of lumacaftor and/or ivacaftor on breastfed infants. ORKAMBI should only be used during breastfeeding if the potential benefit to the patient outweighs the potential risk to the breastfed infant.

**Menstrual abnormalities**
Women taking ORKAMBI, particularly those on hormonal contraceptives, may have an increased incidence of combined menstrual abnormality events, such as amenorrhea, dysmenorrhea, menorrhagia, menstruation irregular, metrorrhagia, oligomenorrhea, and polymenorrhea (see **ADVERSE REACTIONS** and **DRUG INTERACTIONS**).

**Pediatrics (<2 years of age)**
The safety and efficacy of ORKAMBI in patients younger than 2 years of age have not been evaluated.

**Geriatrics (≥65 years of age)**
The safety and efficacy of ORKAMBI in patients age 65 years and older have not been evaluated.

**Monitoring and Laboratory Tests**

**Transaminase (ALT or AST) Elevations and Monitoring**
Elevated transaminases have been reported in patients with CF receiving ORKAMBI (see **ADVERSE REACTIONS**). Because an association with liver injury cannot be excluded, assessments of liver function tests (ALT, AST, and bilirubin) are recommended before initiating ORKAMBI, every three months during the first year of treatment, and annually thereafter. For patients with a history of transaminase or bilirubin elevations, more frequent monitoring of liver function tests should be considered.

Patients who develop increased transaminase or bilirubin levels should be closely monitored until the abnormalities resolve. Dosing should be interrupted in patients with ALT or AST of greater than 5 x upper limit of normal (ULN). Dosing should also be interrupted in patients with ALT or AST elevations greater than 3 x ULN when associated with bilirubin elevations greater than 2 x ULN. Following resolution of transaminase elevations, consider the benefits and risks of resuming ORKAMBI dosing.

Patients should be advised to contact their doctor immediately if they develop symptoms suggestive of increased transaminases (e.g., abdominal pain, anorexia, jaundice, dark urine, pale stools, and pruritus).

Patients with advanced liver disease should be closely monitored while using ORKAMBI.

**Blood Pressure Monitoring**
ORKAMBI is associated with increases in blood pressure (see **ADVERSE REACTIONS** and **ACTION AND CLINICAL PHARMACOLOGY**, **Cardiac Electrophysiology and Hemodynamics**). Blood pressure should be monitored periodically during treatment.
Respiratory
Clinical experience in patients with \( \text{ppFEV}_1 < 40 \) is limited, and additional monitoring of these patients is recommended during initiation of therapy (see \textbf{WARNINGS AND PRECAUTIONS} and \textbf{ADVERSE REACTIONS}).

ADVERSE REACTIONS

Adverse Drug Reaction Overview
The safety profile of ORKAMBI is based on the pooled data from 1108 patients with CF 12 years and older who were homozygous for the \( F508\text{del} \) mutation in the \( CFTR \) gene and who received at least 1 dose of study drug in 2 double-blind, placebo-controlled, Phase 3 clinical studies, each with 24 weeks of treatment (Trials 1 and 2). A total of 738 patients received lumacaftor/ivacaftor [369 patients received ORKAMBI (lumacaftor 400 mg q12h in combination with ivacaftor 250 mg q12h) and 369 patients received lumacaftor 600 mg qd in combination with ivacaftor 250 mg q12h] and 370 patients received placebo. Of the 1108 patients, 49% were female and 99% were Caucasian.

The proportion of patients who prematurely discontinued study drug due to adverse events was 5% for ORKAMBI-treated patients and 2% for placebo-treated patients.

The most common adverse reactions experienced by patients who received ORKAMBI in the pooled, placebo-controlled, Phase 3 studies were dyspnea (13%), nasopharyngitis (13%), nausea (13%), diarrhea (12%), and upper respiratory tract infection (10%).

Serious adverse reactions, whether considered drug-related or not by the investigators, that occurred in patients treated with ORKAMBI included pneumonia, hemoptysis, cough, increased blood creatine phosphokinase, and transaminase elevations. These occurred in 1% or less of patients.

The safety profile of ORKAMBI from a 24-week, open-label, multicentre Phase 3 study (Trial 3) in 58 patients aged 6 through 11 years with CF who are homozygous for the \( F508\text{del-CFTR} \) mutation, was similar to that observed in Trials 1 and 2.

The safety profile of ORKAMBI from a 24-week, open-label, multicentre Phase 3 trial (Trial 4) in 60 patients ages 2 through 5 years with CF who were homozygous for the \( F508 \text{ del-CFTR} \) mutation was generally consistent to that observed in studies in patients aged 6-11 years.

Clinical Trial Adverse Drug Reactions
Because clinical trials are conducted under very specific conditions the adverse reaction rates observed in the clinical trials of a drug cannot be compared to the rates in the clinical trials of another drug and may not reflect the rates observed in clinical practice. Adverse drug reaction information from clinical trials is useful for identifying drug-related adverse events and for approximating rates.

\textit{Patients with CF 12 Years of Age and Older Who Are Homozygous for the F508del Mutation}
The incidence of adverse reactions below is based upon the pooled analyses of Trials 1 and 2.

Table 1 shows adverse reactions occurring in ≥5% of ORKAMBI-treated patients and at a frequency higher than placebo.

### Table 1: Incidence of Adverse Drug Reactions in ≥5% of ORKAMBI-Treated Patients Who are Homozygous for the F508del Mutation in the CFTR Gene in 2 Placebo-Controlled Phase 3 Clinical Trials of 24 Weeks Duration in Patients 12 Years and older

### Description of Selected Adverse Reactions

**Liver-related Adverse Reactions**

In Trials 1 and 2, in patients 12 years and older, the incidence of maximum transaminase (ALT or AST) levels >8, >5, and >3 x ULN elevations was 0.8%, 1.4%, and 4.3% in patients receiving ORKAMBI, and 0.5%, 1.9%, and 5.1% in placebo-treated patients. Three patients who received ORKAMBI had liver-related serious adverse reactions, including 2 reported as transaminase...
elevations and 1 as hepatic encephalopathy, compared to none in the placebo group. Of these three, one had elevated transaminases (>3 x ULN) associated with bilirubin elevation >2 x ULN. Following discontinuation or interruption of ORKAMBI, transaminases decreased to <3 x ULN (see WARNINGS AND PRECAUTIONS).

Among 6 patients with pre-existing cirrhosis and/or portal hypertension who received ORKAMBI, worsening liver function with increased ALT, AST, bilirubin, and hepatic encephalopathy was observed in one patient. The event occurred within 5 days of the start of dosing and resolved following discontinuation of ORKAMBI (see WARNINGS AND PRECAUTIONS).

During Trial 3, in 58 patients 6 through 11 years, the incidence of maximum transaminase (ALT or AST) levels >8, >5, and >3 x ULN was 5.3%, 8.8%, and 19.3%. No patients had total bilirubin levels >2 x ULN. ORKAMBI dosing was maintained or successfully resumed after interruption in all patients with transaminase elevations, except 1 patient who discontinued treatment permanently.

During Trial 4, in 60 patients 2 through 5 years, the incidence of maximum transaminase (ALT or AST) levels >8, >5, and >3 x ULN was 8.3%, 11.7%, and 15.0%. No patients had total bilirubin levels > 2 x ULN. Three patients discontinued lumacaftor/ivacaftor treatment permanently due to transaminase elevations.

Respiratory Adverse Reactions
During Trials 1 and 2, the incidence of respiratory symptom-related adverse reactions (e.g., chest discomfort, dyspnea, and respiration abnormal) was more common in patients treated with ORKAMBI (22%) compared to patients who received placebo (14%). The incidence of these adverse reactions was more common in patients treated with ORKAMBI with lower pre-treatment FEV1. In patients treated with ORKAMBI, approximately three-quarters of the events began during the first week of treatment (see WARNINGS AND PRECAUTIONS).

During Trial 3, in 58 patients aged 6 through 11 years (mean baseline ppFEV1 was 91.4), the incidence of respiratory symptom-related adverse reactions was 3% (2/58).

During Trial 4, in 60 patients aged 2 through 5 years, the incidence of respiratory symptom-related adverse reactions was 5% (3/60 subjects).

Menstrual abnormalities
In Trials 1 and 2, the incidence of combined menstrual abnormality events (amenorrhea, dysmenorrhea, menorrhagia, menstruation irregular, metrorrhagia, oligomenorrhea, and polymenorrhea) was more common in female patients treated with ORKAMBI (10.4%) compared to placebo (1.7%). These events occurred more frequently in the subset of female patients who were taking hormonal contraceptives (26.8%) compared to patients who were not taking hormonal contraceptives (3.2%) (see WARNINGS AND PRECAUTIONS and DRUG INTERACTIONS).
**Increased Blood Pressure**

In Trial 1 and Trial 2, the 24-week, placebo-controlled, Phase 3 studies, adverse reactions related to increased blood pressure (e.g., hypertension, blood pressure increased) were reported in 1.1% (4/369) of patients treated with ORKAMBI and in no patients who received placebo (0/370).

A placebo-adjusted mean increase from baseline in trough systolic blood pressure of 3.1 mmHg was observed at Week 24 in patients receiving ORKAMBI. The proportion of subjects with at least one treatment-emergent systolic blood pressure value >140 mmHg was higher in patients receiving ORKAMBI (10.9%) than in the placebo group (5.4%).

A placebo-adjusted mean increase from baseline in trough diastolic blood pressure of 1.7 mmHg was observed at Week 24 in patients receiving ORKAMBI. The proportion of subjects with at least one treatment-emergent diastolic blood pressure value >90 mmHg was higher in patients receiving ORKAMBI (4.9%) than in the placebo group (1.9%).

**Decreased Heart Rate**

In Trial 1 and Trial 2, serial ECG recordings were performed on Days 1 and 15. In patients treated with ORKAMBI, maximum placebo-adjusted decrease in mean heart rate of 6 and 5 beats per minute (bpm) from baseline were observed on Day 1 and Day 15, respectively. The percentage of patients with heart rate values <50 bpm on treatment was 10.0% for patients who received ORKAMBI compared to 4.9% for patients who received placebo (see WARNINGS AND PRECAUTIONS, Cardiovascular and Monitoring and Laboratory Tests, DRUG INTERACTIONS, ACTION AND CLINICAL PHARMACOLOGY, Cardiac Electrophysiology and Hemodynamics).

**Post-Market Adverse Reactions**

The following additional adverse reactions were observed in a placebo-controlled clinical trial in patients aged 6 through 11 years receiving ORKAMBI: pulmonary exacerbation, productive cough, nasal congestion, oropharyngeal pain, upper abdominal pain, headache, sputum increased, and rhinitis. A transient post-dose ppFEV₁ decline was also observed. Increased incidence of transaminase elevations were also observed compared to previous clinical trials in patients aged 12 years and older.

Post-marketing cases of liver function decompensation including liver failure leading to death have been reported in patients with CF who have pre-existing cirrhosis with portal hypertension who were treated with ORKAMBI (see WARNINGS AND PRECAUTIONS).

**DRUG INTERACTIONS**

**Overview**

Lumacaftor is a strong inducer of CYP3A. Ivacaftor is a weak inhibitor of CYP3A when given as monotherapy. The net effect of lumacaftor/ivacaftor therapy is expected to be strong CYP3A induction. Co-administration of lumacaftor with ivacaftor, a sensitive CYP3A substrate, decreased ivacaftor exposure by approximately 80%.
Lumacaftor is not extensively metabolized in humans with the majority of lumacaftor excreted unchanged in the feces. In vitro and in vivo data indicate that lumacaftor is mainly metabolized via oxidation and glucuronidation. Ivacaftor is extensively metabolized in humans. In vitro and in vivo data indicate that ivacaftor is primarily metabolized by CYP3A.

Drug interaction studies were performed in adults with lumacaftor/ivacaftor and other drugs likely to be co-administered or drugs commonly used as probes for pharmacokinetic interaction studies.

**Drug-Drug Interactions**

Based on exposure and indicated doses, the drug interaction profile is considered to be the same for all dosage strengths and forms.

The drugs listed in Table 2 are based on either drug interaction case reports or studies, or potential interactions due to the expected magnitude and seriousness of the interaction (i.e., those identified as contraindicated).

Legend: CT = Clinical Trial; T = Theoretical

*CYP2B6 and CYP2C Substrates*

_in vitro_ studies suggest that lumacaftor has the potential to induce CYP2B6, CYP2C8, CYP2C9, and CYP2C19; inhibition of CYP2C8 and CYP2C9 has also been observed _in vitro_. Additionally, _in vitro_ studies suggest that ivacaftor may inhibit CYP2C9. Therefore, concomitant use of ORKAMBI with CYP2B6, CYP2C8, CYP2C9, and CYP2C19 substrates may alter the exposure of these substrates.

*Drug-Food Interaction*

Increased exposure to lumacaftor and ivacaftor was observed following administration with food compared to fasting conditions. ORKAMBI should be taken with fat-containing food (see ACTION AND CLINICAL PHARMACOLOGY, Pharmacokinetics).

*Drug-Herb Interactions*

Co-administration of ORKAMBI with herbal products that strongly induce CYP3A (e.g., St. John’s wort) may decrease efficacy and is not recommended.

*Drug-Lifestyle Interactions*

*Effects on Ability to Drive and Use Machines*

ORKAMBI is not expected to have an impact on the ability to drive and use machines.

**DOSAGE AND ADMINISTRATION**

*Dosing Considerations*

ORKAMBI should only be administered to patients who have a mutation in the CFTR gene listed in INDICATIONS AND CLINICAL USE.

ORKAMBI should only be prescribed by physicians with experience in the treatment of cystic fibrosis. If the patient’s genotype is unknown, an accurate and validated genotyping method should be performed to confirm the presence of the F508del mutation on both alleles of the
CFTR gene.

**Recommended Dose and Dosage Adjustment**

</tr>
</tbody>
</table>

ORKAMBI granules and tablets should be taken with fat-containing food. A fat-containing meal or snack should be consumed just before or just after dosing (see DOSAGE AND ADMINISTRATION, Method of Administration).

**Dosage Adjustment for Patients with Hepatic Impairment**

For dose adjustments for patients with hepatic impairment refer to Table 4.

Studies have not been conducted in patients with severe hepatic impairment (Child-Pugh Class C), but exposure is expected to be higher than in patients with moderate hepatic impairment. Therefore, use with caution after weighing the risks and benefits of treatment and reduce the dose to a maximum dose of 1 tablet in the morning and 1 tablet in the evening, or less frequently, or 1 packet of granules per day or less frequently (see WARNINGS AND PRECAUTIONS, Monitoring and Laboratory Tests, ADVERSE REACTIONS, and ACTION AND CLINICAL PHARMACOLOGY).

**Patients with Elevated Liver Function Tests**
Dosing should be interrupted and laboratory tests closely followed in patients with ALT or AST greater than 5 x upper limit of normal (ULN) when not associated with elevated bilirubin.
Dosing should also be interrupted and laboratory tests closely followed in patients with ALT or
AST elevations greater than 3 x ULN when associated with bilirubin elevations greater than 2 x ULN.

**Dosage Adjustment for Patients with Renal Impairment**
No dose adjustment is necessary for patients with mild to moderate renal impairment. Caution is recommended while using ORKAMBI in patients with severe renal impairment (creatinine clearance less than or equal to 30 mL/min) or end-stage renal disease (see **WARNINGS AND PRECAUTIONS** and **ACTION AND CLINICAL PHARMACOLOGY**).

**Dosage Adjustment for Patients Taking CYP3A Inhibitors**
No dose adjustment is necessary when CYP3A inhibitors are initiated in patients currently taking ORKAMBI. However, when initiating ORKAMBI in patients currently taking strong CYP3A inhibitors (e.g., itraconazole), reduce ORKAMBI dose to 1 tablet daily or 1 packet of granules every other day as appropriate for the first week of treatment. Following this period, continue with the recommended daily dose.

If ORKAMBI is interrupted for more than 1 week and then re-initiated while taking strong CYP3A inhibitors, reduce ORKAMBI dose to 1 tablet daily or 1 packet of granules every other day for the first week of treatment re-initiation (see **DRUG INTERACTIONS**). Following this period, continue with the recommended daily dose.

**Method of administration**
For oral use.

A fat-containing meal or snack should be consumed just before or just after dosing.

Meals and snacks recommended in CF guidelines or meals recommended in standard nutritional guidelines contain adequate amounts of fat. A serving size of foods appropriate for age from a typical CF diet should be given. Examples of fat-containing food: meals that contain fat that have been prepared with butter or oils, meals that have-eggs, nuts, whole-dairy products (such as whole-milk, cheese, and yogurt), or meats.

*Film-coated tablets*
Patients should be instructed to swallow the tablets whole (e.g., patients should not chew, break, or dissolve the tablets).

*Granules*
The entire content of each packet of granules should be mixed with 5 mL (one teaspoon) of age appropriate soft food or liquid and the mixture completely consumed. Some examples of soft foods include puréed fruits or vegetables, flavored yogurt or pudding, applesauce, and milk or juice (except grapefruit). Food should be at 5 to 25°C. Each packet is for single use only. Once mixed, the product has been shown to be stable for one hour, and therefore should be ingested during this period and not stored for future use.

**Missed Dose**
If less than 6 hours have passed since the missed dose, the scheduled dose of ORKAMBI should
be taken with fat containing food. If more than 6 hours have passed, the patient should be instructed to wait until the next scheduled dose. Patients should be instructed not to take a double dose to make up for the forgotten dose.

**OVERDOSAGE**

The highest repeated dose was lumacaftor 1000 mg once daily/ivacaftor 450 mg q12h administered to 49 healthy subjects for 7 days in a trial evaluating the effect of ORKAMBI on electrocardiograms (ECGs). Adverse events reported at an increased incidence of ≥5% compared to the lumacaftor 600 mg/ivacaftor 250 mg dosing period and placebo included: headache (29%), transaminase increased (18%), and generalized rash (10%).

No specific antidote is available for overdose with ORKAMBI. Treatment of overdose consists of general supportive measures including monitoring of vital signs and observation of the clinical status of the patient.

For management of a suspected drug overdose, contact your regional Poison Control Centre.

**ACTION AND CLINICAL PHARMACOLOGY**

**Mechanism of Action**

The CFTR protein is a chloride channel present at the surface of epithelial cells in multiple organs. The F508del mutation results in protein misfolding by causing a defect in cellular processing and trafficking that reduces the quantity of CFTR at the cell surface. The small amount of F508del-CFTR that reaches the cell surface is less stable and has low channel-open probability (defective channel gating) compared to wild-type CFTR protein.

Lumacaftor is a CFTR corrector that is believed to improve the conformational stability of F508del-CFTR protein, resulting in increased processing and trafficking of mature F508del-CFTR protein to the cell surface. Ivacaftor is a CFTR potentiator that facilitates increased chloride transport by potentiating the channel-open probability (or gating) of the CFTR protein at the cell surface. *In vitro* studies have demonstrated that both lumacaftor and ivacaftor act directly on the CFTR protein in primary human bronchial epithelial cultures and other cell lines harbouring the F508del-CFTR mutation to increase the quantity, stability, and function of F508del-CFTR at the cell surface, resulting in increased chloride ion transport. *In vitro* responses do not necessarily correspond to *in vivo* pharmacodynamic response or clinical benefit.

**Pharmacodynamics**

*Cardiac Electrophysiology and Hemodynamics*

The effect of multiple doses of lumacaftor 600 mg once daily/ivacaftor 250 mg q12h for 7 days, followed by lumacaftor 1000 mg once daily/ivacaftor 450 mg q12h for an additional 7 days was evaluated in a randomized, placebo- and active-controlled parallel group, ascending dose thorough ECG study in 168 healthy subjects. No meaningful changes in the QTc interval, the
QRS duration, or the PR interval were observed with either lumacaftor 600 mg once daily/ivacaftor 250 mg q12h or lumacaftor 1000 mg once daily/ivacaftor 450 mg q12h.

A decrease in heart rate was observed in subjects who received lumacaftor/ivacaftor. On Day 7, during treatment with lumacaftor 600 mg once daily/ivacaftor 250 mg q12h, statistically significant negative mean differences from placebo were observed at 9 of 10 time points, with a maximum mean difference from placebo of -7.86 bpm (90% CI -10.23, -5.49) at 3 hours post-dosing. On Day 14, during treatment with lumacaftor 1000 mg once daily/ivacaftor 450 mg q12h, statistically significant negative mean differences from placebo were observed at 4 of 10 time points, with a maximum mean difference from placebo of -4.09 bpm (90% CI -6.87, -1.31) at 6 hours.

Blood pressure assessments were performed prior to dosing on every treatment day. Placebo-adjusted mean increases from baseline in trough systolic blood pressure of 2 to 4 mmHg from Day 2 to Day 15 were observed in subjects who received lumacaftor/ivacaftor.

Placebo-adjusted mean increases from baseline in trough diastolic blood pressure of 2 to 6 mmHg from Day 2 to Day 15 were observed in subjects who received lumacaftor/ivacaftor (see WARNINGS AND PRECAUTIONS, Cardiovascular and Monitoring and Laboratory Tests; ADVERSE REACTIONS, Blood Pressure).

**Sweat Chloride Evaluation**
Changes in sweat chloride in response to relevant doses of lumacaftor alone or in combination with ivacaftor were evaluated in a double-blind, placebo-controlled, Phase 2 clinical trial in patients with CF 18 years of age and older either homozygous or heterozygous for the F508del mutation. In that trial, 10 patients (homozygous for F508del) completed dosing with lumacaftor alone 400 mg q12h for 28 days followed by the addition of ivacaftor 250 mg q12h for an additional 28 days and 25 patients (homozygous or heterozygous for F508del) completed dosing with placebo. The treatment difference between lumacaftor 400 mg q12h alone and placebo evaluated as mean change in sweat chloride from baseline to Day 28 compared to placebo was -8.2 mmol/L (95% CI -14, -2). The treatment difference between the combination of lumacaftor 400 mg/ivacaftor 250 mg q12h and placebo evaluated as mean change in sweat chloride from baseline to Day 56 compared to placebo was -11 mmol/L (95% CI -18, -4).

Changes in sweat chloride in response to lumacaftor/ivacaftor were evaluated in a 24-week, open-label Phase 3 clinical trial (Trial 3) in 58 patients with CF, aged 6 through 11 years (homozygous for F508del) who received lumacaftor 200 mg/ivacaftor 250 mg q12h for 24 weeks. Patients treated with lumacaftor/ivacaftor had a reduction in sweat chloride at Day 15 that was sustained through Week 24. The within-group LS mean absolute change from baseline in sweat chloride was -20.4 mmol/L at Day 15 and -24.8 mmol/L at Week 24. In addition, sweat chloride was also assessed after a 2-week washout period to evaluate the off-drug response. The within-group LS mean absolute change in sweat chloride from Week 24 to Week 26 following the 2-week washout period was 21.3 mmol/L.

Changes in sweat chloride in response to lumacaftor/ivacaftor were evaluated in a 24 week, open-label Phase 3 clinical study (Trial 4) in 60 patients with CF, aged 2 through 5 years
(homozygous for $F508del$) who received either lumacaftor 100 mg/ivacaftor 125 mg every 12 hours (subjects <14 kg in weight) or lumacaftor 150 mg/ivacaftor 188 mg every 12 hours (subjects ≥14 kg in weight) for 24 weeks. Treatment with lumacaftor/ivacaftor demonstrated a reduction in sweat chloride at Week 4 through Week 24. The mean absolute change from baseline in sweat chloride was –31.7 mmol/L (95% CI: –35.7, -27.6) at Week 24. In addition, sweat chloride was also assessed after a 2 week washout period to evaluate the off drug response. The mean absolute change in sweat chloride from Week 24 at Week 26 following the 2 week washout period was an increase of 33.0 mmol/L (95% CI: 28.9, 37.1). This change represents a return to baseline after treatment washout.

There was no direct correlation between decrease in sweat chloride levels and improvement in lung function (ppFEV$_1$).

* Based on tablet formulation
† Based on lumacaftor 200 mg q12h/ivacaftor 250 mg q12h studied in healthy subjects

The exposure (AUC) of lumacaftor is approximately 2-fold higher in healthy adult volunteers compared to exposure in patients with CF. The exposure of ivacaftor is similar between healthy adult volunteers and patients with CF. After twice-daily dosing, steady-state plasma concentrations of lumacaftor and ivacaftor in healthy subjects were generally reached after approximately 7 days of treatment, with an accumulation ratio of approximately 1.9 for lumacaftor. The steady-state exposure of ivacaftor is lower than that of Day 1 due to the CYP3A induction effect of lumacaftor. The apparent terminal half-life of lumacaftor is approximately 26 hours. The typical apparent clearance, CL/F (CV), of lumacaftor was estimated to be 2.38 L/hr (29.4%) for patients with CF. In healthy subjects, the half-life of ivacaftor when given with lumacaftor is approximately 9 hours. The typical CL/F (CV) of ivacaftor when given in combination with lumacaftor was estimated to be 25.1 L/hr (40.5%) for patients with CF.

**Absorption**

**Tablet Formulation**

Following multiple oral doses of lumacaftor, the exposure of lumacaftor generally increased proportional to dose over the range of 50 mg to 1000 mg every 24 hours. Following administration of a single 400 mg/250 mg dose of ORKAMBI with a high-fat, high-calorie meal, the AUC$_T$ and $C_{\text{max}}$ of lumacaftor increased by 1.6-fold and 2.2-fold, respectively when compared to administration under fasted conditions. The median (range) $t_{\text{max}}$ of lumacaftor is...
approximately 4.0 hours (2.0; 9.0) in the fed state.

Following multiple oral dose administration of ivacaftor in combination with lumacaftor, the exposure of ivacaftor generally increased with doses of 150 mg every 12 hours to 250 mg every 12 hours. Following administration of a single 400 mg/250 mg dose of ORKAMBI with a high-fat, high-calorie meal, the AUC_T and C_max of ivacaftor increased by 2.6-fold and 3.7-fold, respectively when compared to administration under fasted conditions. The median (range) t_max of ivacaftor is approximately 4.0 hours (2.0; 6.0) in the fed state.

Granule Formulation
Following administration of a single 100 mg/125 mg dose of ORKAMBI with a high-fat, high-calorie meal to healthy adult volunteers, the AUC_T and C_max of lumacaftor increased by 1.2-fold and 1.5-fold, respectively when compared to administration under fasted conditions. The median (range) t_max of lumacaftor is approximately 6.0 hours (2.0; 12.0) in the fed state.

Following administration of a single 100 mg/125 mg dose of ORKAMBI with a high-fat, high-calorie meal to healthy adult volunteers, the AUC_T and C_max of ivacaftor increased by 1.8-fold and 1.9-fold, respectively when compared to administration under fasted conditions. The median (range) t_max of ivacaftor is approximately 6.0 hours (3.0; 12.0) in the fed state.

Distribution
Lumacaftor is approximately 99% bound to plasma proteins, primarily to albumin. After oral administration of 400 mg every 12 hours in CF patients in a fed state, the typical apparent volumes of distribution for the central and peripheral compartments (CV) were estimated to be 23.5 L (48.7%) and 33.3 L (30.5%), respectively.

Ivacaftor is approximately 99% bound to plasma proteins, primarily to alpha 1-acid glycoprotein and albumin. Ivacaftor does not bind to human red blood cells.

After oral administration of ivacaftor 250 mg every 12 hours in combination with lumacaftor, the typical apparent volumes of distribution for the central and peripheral compartments (CV) were estimated to be 95.0 L (53.9%) and 201 L (26.6%), respectively.

Metabolism
Lumacaftor is not extensively metabolized in humans with the majority of lumacaftor excreted unchanged in the feces. In vitro and in vivo data indicate that lumacaftor is mainly metabolized via oxidation and glucuronidation.

Ivacaftor is extensively metabolized in humans. In vitro and in vivo data indicate that ivacaftor is primarily metabolized by CYP3A. M1 and M6 are the two major metabolites of ivacaftor in humans. M1 has approximately 1/6th the potency of ivacaftor and is considered pharmacologically active. M6 has less than 1/50th the potency of ivacaftor and is not considered pharmacologically active.

Elimination
Following oral administration of lumacaftor, the majority of lumacaftor (51%) is excreted
unchanged in the feces. In a human pharmacokinetic study with lumacaftor alone, there was minimal elimination of lumacaftor and its metabolites in urine (only 8.6% of total radioactivity was recovered in the urine with 0.18% as unchanged parent).

Following oral administration of ivacaftor alone, the majority of ivacaftor (88%) is eliminated in the feces after metabolic conversion. The major metabolites, M1 and M6, accounted for approximately 65% of the total dose eliminated with 22% as M1 and 43% as M6. In a human pharmacokinetic study with ivacaftor alone, there was minimal elimination of ivacaftor and its metabolites in urine (only 6.6% of total radioactivity was recovered in the urine). There was negligible urinary excretion of ivacaftor as unchanged parent.

**Special Populations and Conditions**

**Pediatrics**

The following exposures are comparable between adults and the pediatric population based on population pharmacokinetics (PK) analyses as presented in Table 6.

</table>

**Gender**

The effect of gender was evaluated using a population pharmacokinetics analysis of data from clinical studies of lumacaftor given in combination with ivacaftor. Results indicate no clinically relevant difference in pharmacokinetic parameters for lumacaftor and ivacaftor between males and females. No dose adjustments of ORKAMBI are necessary based on gender.

**Hepatic Insufficiency**

The impact of mild hepatic impairment (Child-Pugh Class A, score 5 to 6) on pharmacokinetics of lumacaftor given in combination with ivacaftor has not been studied, but the increase in exposure is expected to be less than 50%. Therefore, no dose adjustment is recommended for
patients with mild hepatic impairment.

Following multiple doses of lumacaftor/ivacaftor for 10 days, subjects with moderately impaired hepatic function (Child-Pugh Class B, score 7 to 9) had higher exposures (AUC\(_{0-12\text{hr}}\) by approximately 50% and C\(_{\text{max}}\) by approximately 30%) compared with healthy subjects matched for demographics. Therefore, a dose reduction is recommended for these patients (see DOSAGE AND ADMINISTRATION).

Studies have not been conducted in patients with severe hepatic impairment (Child-Pugh Class C, score 10 to 15), but exposure is expected to be higher than in patients with moderate hepatic impairment. Therefore, ORKAMBI should be used with caution in patients with severe hepatic impairment after weighing the risks and benefits of treatment (see WARNINGS AND PRECAUTIONS and ADVERSE REACTIONS). A dose reduction is recommended for these patients (see DOSAGE AND ADMINISTRATION).

Renal Insufficiency
Pharmacokinetic studies have not been performed with ORKAMBI in patients with renal impairment. However, in human pharmacokinetic studies with lumacaftor or ivacaftor alone, there was negligible urinary excretion of lumacaftor or ivacaftor as unchanged parent (see Elimination). Therefore, no dose adjustments for ORKAMBI are recommended for mild to moderate renal impairment. However, caution is recommended when administering ORKAMBI to patients with severe renal impairment (creatinine clearance less than or equal to 30 mL/min) or end-stage renal disease (see WARNINGS AND PRECAUTIONS).

STORAGE AND STABILITY
Store at or below 30°C.

Keep out of the sight and reach of children.

SPECIAL HANDLING INSTRUCTIONS

Disposal of unused/expired medicines
The release of pharmaceuticals in the environment should be minimized. Medicines should not be disposed of via wastewater and disposal through household waste should be avoided. Use established “collection systems” if available.

DOSAGE FORMS, COMPOSITION AND PACKAGING

Dosage forms
ORKAMBI (lumacaftor/ivacaftor) is supplied in the following dosage forms:
- Tablets
  - 100 mg/125 mg tablets
  - 200 mg/125 mg tablets
- **Granules**
  - 100 mg/125 mg granules
  - 150 mg/188 mg granules

**Tablets**

*100 mg/125 mg tablets*
These are pink, oval-shaped film-coated tablets for oral administration, printed with “1V125” in black ink on one side and plain on the other.

*200 mg/125 mg tablets*
These are pink, oval-shaped film-coated tablets for oral administration, printed with “2V125” in black ink on one side and plain on the other.

**Granules**

*100 mg/125 mg granules and 150 mg/188 mg granules*
These are white to off-white granules for oral administration and enclosed in unit dose packets.

**Composition**

*200 mg/125 mg tablets and 100 mg/125 mg tablets*
Each tablet contains 200 mg of lumacaftor and 125 mg of ivacaftor, or 100 mg of lumacaftor and 125 mg of ivacaftor, and the following non-medicinal ingredients: cellulose, microcrystalline; croscarmellose sodium; hypromellose acetate succinate; magnesium stearate; povidone; and sodium lauryl sulfate. The tablet film coat contains carmine, FD&C Blue #1, FD&C Blue #2, polyethylene glycol, polyvinyl alcohol, talc, and titanium dioxide. The printing ink contains ammonium hydroxide, iron oxide black, propylene glycol, and shellac.

*100 mg/125 mg granules and 150 mg/188 mg granules*
The granules are supplied in unit dose packets. Each packet of granules contains 100 mg of lumacaftor and 125 mg of ivacaftor, or 150 mg of lumacaftor and 188 mg of ivacaftor, and the following non-medicinal ingredients: cellulose, microcrystalline; croscarmellose sodium; hypromellose acetate succinate; povidone; sodium lauryl sulfate.

**Packaging**
The following pack sizes are available:

**Film-coated tablets:**

*100 mg/125 mg tablets*
112 tablets (supplied in a box containing 4 cartons, with each carton containing 7 blister strips with 4 tablets per strip).

*200 mg/125 mg tablets*
112 tablets (supplied in a box containing 4 cartons, with each carton containing 7 blister strips, with 4 tablets per strip).

**Granules:**

*100 mg/125 mg granules*
56 packets (supplied in a box containing 4 wallets, with each wallet containing 14 packets of 100 mg/125 mg granules per printed foil laminate packet).

150 mg/188 mg granules
56 packets (supplied in a box containing 4 wallets, with each wallet containing 14 packets of 150 mg/188 mg granules per printed foil laminate packet).
PART II: SCIENTIFIC INFORMATION

PHARMACEUTICAL INFORMATION

Drug Substance

Proper name: lumacaftor/ivacaftor (INN)

Chemical name:

_lumacaftor_: 3-[6-([1-(2,2-difluoro-1,3-benzodioxol-5-y1)cyclopropyl]carbonyl)amino]-3-methylpyridin-2-yl]benzoic acid

_ivacaftor_: N-(2,4-di-tert-butyl-5-hydroxyphenyl)-1,4-dihydro-4-oxoquinoline-3-carboxamide

Molecular formula and molecular mass:

_lumacaftor_: C_{24}H_{18}F_{2}N_{2}O_{5}; 452.41

_ivacaftor_: C_{24}H_{28}N_{2}O_{3}; 392.49

Structural formula:

![Structural formula of lumacaftor and ivacaftor](image)

Physicochemical properties: Lumacaftor is a white to off-white powder that is practically insoluble in water (0.02 mg/mL). Ivacaftor is a white to off-white powder that is practically insoluble in water (<0.05 microgram/mL).
CLINICAL TRIALS

Study demographics and trial design

The trial design and patient demographics for the ORKAMBI clinical trials are summarized in Table 7 below.

* n=Number of patients randomized and dosed
† n=Number of patients dosed
Trial 1
Trial 1 evaluated 549 patients with CF aged 12 years and older (mean age 25.1 years) with percent predicted FEV₁ (ppFEV₁) at screening between 40-90 [mean ppFEV₁ 60.7 at baseline (range: 31.1 to 94.0)]. All patients were tested for the CF genotype at screening; eligible patients had the F508del mutation on both alleles. Patients with a history of colonization with organisms such as Burkholderia cenocepacia, Burkholderia dolosa, or Mycobacterium abscessus, or who had 3 or more abnormal liver function tests (ALT, AST, AP, GGT ≥3 x the ULN or total bilirubin ≥2 x the ULN) were excluded.

Trial 2
Trial 2 evaluated 559 patients with CF aged 12 years and older (mean age 25.0 years) with ppFEV₁ at screening between 40-90 [mean ppFEV₁ 60.5 at baseline (range: 31.3 to 99.8)]. All patients were tested for the CF genotype at screening; eligible patients had the F508del mutation on both alleles. Patients with a history of colonization with organisms such as Burkholderia cenocepacia, Burkholderia dolosa, or Mycobacterium abscessus, or who had 3 or more abnormal liver function tests (ALT, AST, AP, GGT ≥3 x the ULN) were excluded.

Trial 3
Trial 3 evaluated 58 patients with CF aged 6 through 11 years (mean age 9.1 years) with ppFEV₁ at screening ≥40 and weight >15 kg. Subjects had a mean baseline ppFEV₁ of 91.4 (range: 55 to 122.7). All patients were tested for the CF genotype at screening; eligible patients had the F508del mutation on both alleles. Patients who had 3 or more abnormal liver function tests (ALT, AST, AP, GGT ≥3 x the ULN), or ALT or AST >5 x ULN, or total bilirubin >2 x the ULN were excluded.

Trial 4
Trial 4 was an open-label, safety trial that evaluated 60 patients with CF aged 2 through 5 years at screening (mean age at baseline 3.7 years) homozygous for F508del mutation. According to their weight at screening, patients were administered granules mixed with food every 12 hours, at a dose of lumacaftor 100 mg/ivacaftor 125 mg granules for patients weighing less than 14 kg or lumacaftor 150 mg/ivacaftor 188 mg for patients weighing 14 kg or greater, for 24 weeks in addition to their prescribed CF therapies. All patients had a weight of greater than 8 kg. Patients who had an abnormal liver function test (ALT, AST or total bilirubin >2x ULN) were excluded. In order to evaluate off drug effects, patients had a safety follow-up visit following a 2-week washout period.

Study results
Trials 1 and 2 - Patients with CF aged 12 years and older who are Homozygous for the F508del Mutation in the CFTR Gene

Efficacy
The efficacy of ORKAMBI in patients with CF who are homozygous for the F508del mutation in the CFTR gene was evaluated in two randomized, double-blind, placebo-controlled Phase 3 clinical trials in which 1108 clinically stable patients with CF were randomized and received at least 1 dose of study drug; 369 of these patients were randomized to the ORKAMBI (lumacaftor 400 mg q12h/ivacaftor 250 mg q12h) dose. Patients in both trials were randomized 1:1:1 to
receive lumacaftor 600 mg once daily/ivacaftor 250 mg q12h; or ORKAMBI (lumacaftor 400 mg q12h/ivacaftor 250 mg q12h); or placebo. Patients took the study drug with fat-containing food for 24 weeks in addition to their prescribed CF therapies (e.g., bronchodilators, inhaled antibiotics, dornase alfa, and hypertonic saline). Patients from these trials were eligible to roll over into an uncontrolled extension study.

The primary efficacy endpoint in both studies was improvement in lung function as determined by the absolute change from baseline in ppFEV₁ at Week 24, assessed as the average of the treatment effects at Week 16 and at Week 24.

In both trials, treatment with ORKAMBI resulted in a statistically significant improvement in ppFEV₁. The treatment difference between ORKAMBI and placebo for the mean absolute change in ppFEV₁ from baseline at Week 24 (assessed as the average of the treatment effects at Week 16 and at Week 24) was 2.6 percentage points in Trial 1 ($P=0.0003$) and 3.0 percentage points in Trial 2 ($P<0.0001$) (Figure 1). These changes persisted throughout the 24-week treatment period (Figure 1). Improvements in ppFEV₁ were observed regardless of age, disease severity, sex, and geographic region.

**Figure 1. Absolute Change From Baseline at Each Visit in Percent Predicted FEV₁ in Trial 1 and Trial 2**

![Graph showing absolute change from baseline in percent predicted FEV₁](image)

**Other Clinical Endpoints**

Other efficacy variables included relative change from baseline in ppFEV₁ at Week 24, assessed as the average of the treatment effects at Week 16 and at Week 24; absolute change from baseline in BMI at Week 24; absolute change from baseline in CFQ-R Respiratory Domain at Week 24 (the CFQ-R is a disease-specific, patient-reported, health-related quality-of-life measure for cystic fibrosis consisting of generic and CF-specific scales). The respiratory domain of the CFQ-R was used as an assessment tool for clinically relevant respiratory symptoms such as cough, wheeze, congestion, sputum production, and difficulty breathing. The proportion of patients achieving $\geq 5\%$ relative change from baseline in ppFEV₁ using the average of Week 16 and Week 24 was also assessed in both trials along with the number of pulmonary exacerbations through Week 24. For the purposes of these trials, a pulmonary exacerbation was defined as a change in antibiotic therapy (IV, inhaled, or oral) for any 4 or more of 12 pre-specified sino-pulmonary signs/symptoms.
Patients treated with ORKAMBI demonstrated statistically significant improvements in relative change in ppFEV₁ and absolute change in BMI (in Trial 2 only) (Table 8).

**Trial 3 - Safety and tolerability study in pediatric patients with CF aged 6 through 11 years homozygous for the F508del mutation in the CFTR gene**

The efficacy of ORKAMBI in children ages 6 through 11 years is extrapolated from efficacy in patients ages 12 years and older homozygous for the F508del mutation in the CFTR gene with support from population pharmacokinetic analyses showing similar drug exposure levels in patients ages 12 years and older and in children ages 6 through 11 years (see Table 6).

Additional safety data were obtained from a 24-week, open-label, Phase 3 clinical trial in 58 patients aged 6 through 11 years, mean age 9 years (Trial 3).
In Trial 3, spirometry (ppFEV₁) was assessed as a planned safety endpoint. The within-group LS mean absolute change from baseline in ppFEV₁ at Week 24 was 2.5 percentage points. At the Week 26 safety follow-up visit (following a planned discontinuation) ppFEV₁ was also assessed. The within-group LS mean absolute change in ppFEV₁ from Week 24 at Week 26 was -3.2 percentage points.

BMI and BMI-for-age z-score were assessed as secondary endpoints. The within-group LS mean absolute change in BMI was 0.64 kg/m² at Week 24 and BMI-for-age z-score was 0.15 at Week 24.

**Trial 4 - Safety and tolerability study in pediatric patients with CF aged 2 through 5 years homozygous for the F508del mutation in the CFTR gene**

The efficacy of ORKAMBI in children ages 2 through 5 years is extrapolated from efficacy in patients ages 6 years and older homozygous for the F508del mutation in the CFTR gene with support from population pharmacokinetic analyses showing similar drug exposure levels in patients ages 6 years and older administered ORKAMBI tablets and in children ages 2 through 5 years (see Table 6) administered ORKAMBI oral granules.

Trial 4, a 24-week, open-label, Phase 3 trial in 60 patients with CF aged 2 through 5 years provided additional safety data as the primary objective.

Spirometry (ppFEV₁) was assessed in subjects more than 3 years of age, however, data were available for only 13 subjects at baseline and at Week 24 with all but 1 subject receiving the higher dose (lumacaftor 150 mg/ivacaftor 188 mg). The mean absolute change from baseline in ppFEV₁ was 0.5 percentage points at Week 24 in the lumacaftor 150 mg /ivacaftor 188 mg group.

Clinical trial outcomes included BMI and BMI-for-age z-score as other secondary endpoints. The absolute change from baseline in BMI and in BMI-for-age z-score were 0.27 kg/m² and 0.29, respectively at Week 24.

**DETAILED PHARMACOLOGY**

Lumacaftor, a CFTR corrector, improved the cellular processing and trafficking of F508del-CFTR to enhance chloride transport in primary cultures of human bronchial epithelial (HBE) cells derived from people with CF homozygous for F508del. Ivacaftor, a CFTR potentiator, potentiated the channel-gating activity (open probability) of the F508del-CFTR channels delivered to the cell surface by lumacaftor to further enhance chloride transport. The magnitude of chloride transport observed with the combination of lumacaftor and ivacaftor treatment was greater than that observed with either agent alone.

**Secondary Pharmacodynamics**

*Lumacaftor*

Lumacaftor did not correct the processing or trafficking of 38 other proteins examined, including other misfolded proteins, ABC-transporters, ion channels, kinases, and G-protein coupled receptors at concentrations up to 10 µM, suggesting that lumacaftor is not a general corrector of
misfolded or normally folded proteins and therefore has a specific effect on CFTR. Lumacaftor was evaluated in vitro for off-target effects on a wide variety of receptors and enzymes in radioligand binding assays, as well as for interactions with a variety of ion channels. Binding activity was limited to the human thromboxane A2 (TXA2) receptor with a $K_i=2.97$ μM and lumacaftor was subsequently demonstrated to be a functional antagonist of TXA2 activity using rat aortic ring preparations. Overall, these results indicate a low potential for lumacaftor-mediated off-target or secondary pharmacodynamic effects.

Although limited by solubility in the test system, lumacaftor was not considered a potent hERG channel blocker (non-statistically significant 0.2% inhibition at maximum soluble concentration of 4.6 μM). The IC$_{50}$ for the inhibitory effect could not be determined due to lack of significant inhibition at the limit of solubility and these results were corroborated in vivo by the lack of any cardiovascular, particularly ECG, findings in telemetered Beagle dogs at single oral doses of 200 mg/kg.

**Ivacaftor**

Ivacaftor was evaluated in vitro for off-target effects on a wide variety of receptors and enzymes in radioligand binding assays, as well as for interactions with a variety of ion channels. Ivacaftor did not potently bind to or alter the function of these targets, indicating a low potential for off-target effects. In electrophysiological studies, ivacaftor inhibited only Ca$_{v}$1.2 (IC$_{50}$=1.3 μM) and Kv1.5 (IC$_{50}$=3.4 μM) with moderate potency and had little or no measurable activity (IC$_{50}$>10 μM) on the other sodium, calcium, and potassium channels tested.

Ivacaftor produced concentration-dependent inhibition of hERG (human ether-à-go-go related gene) tail currents, with an IC$_{15}$ of 5.5 μM, which is higher than the C$_{max}$ (1.5 μM) for ivacaftor at the therapeutic dose. However, no ivacaftor-related QT prolongation was observed in a dog telemetry study at single doses up to 60 mg/kg, or in ECG measurements from repeat-dose studies in dogs up to 1 year at 60 mg/kg/day. Ivacaftor produced dose-related but transient increase in the blood pressure parameters in dogs at single oral doses up to 60 mg/kg.

**Safety Pharmacology**

**Lumacaftor**

Oral administration of lumacaftor did not cause adverse effects on CNS, respiratory systems, or gastrointestinal motility in rats at single oral doses of up to 1000 mg/kg.

**Ivacaftor**

Oral administration of ivacaftor did not cause adverse effects on CNS, or respiratory systems in rats at single oral doses of up to 1000 mg/kg. Ivacaftor did not cause adverse effects on the cardiovascular system in telemetry studies at single oral doses up to 100 mg/kg in rats and 60 mg/kg in dogs. Ivacaftor produced an inhibition of gastric emptying and gastrointestinal transit in rats at single oral doses of 500 and 1000 mg/kg.

**Pharmacokinetics**

The findings from the in vivo studies demonstrated that the absorption of lumacaftor and ivacaftor in mice, rats, rabbits, and dogs is rapid and bioavailability (%F) ranged from 30% to 100%. When co-administered in combination studies in rats and dogs, systemic exposures to
lumacaftor and ivacaftor were similar to exposures achieved when these compounds were administered individually. The apparent permeability of lumacaftor and ivacaftor in Caco-2 cell monolayer was high, which may have contributed to a high oral bioavailability. Neither lumacaftor nor ivacaftor is a substrate for efflux transporter P-gp.

A dose-proportional increase in exposure was observed when lumacaftor and ivacaftor were dosed at lower PK doses; whereas, exposure was generally less than dose proportional at higher doses explored in toxicity studies. No significant sex differences in exposure were observed for either lumacaftor or ivacaftor. Following repeated administration in mice, rats, rabbits, and dogs, there was no evidence of accumulation of lumacaftor; whereas, ivacaftor exposures were higher at steady state compared to single dose exposures and accumulation was evident over time in longer duration repeat-dose toxicity studies. In addition, systemic exposure to ivacaftor’s major metabolites (data not shown) was higher for M1 than for M6 for all 3 species measured (mice, rats, and dogs); however, M1 and M6 exposures were less than ivacaftor in these species.

*In vitro* protein binding of lumacaftor, M28-lumacaftor, ivacaftor, M1-ivacaftor, and M6-ivacaftor, was high (>98%) in mouse, rat, dog, and human plasma. Results from studies with isolated human plasma protein components indicate that these compounds are primarily bound to human serum albumin (HSA). *In vivo*, neither lumacaftor nor ivacaftor bind to melanin-containing tissues (skin and/or eyes). Placental transfer of $^{14}$C-labelled lumacaftor and $^{14}$C-labelled ivacaftor after a single oral dose to pregnant rats and rabbits occurred, but the exposures to ivacaftor in fetuses were low and variable.

Lumacaftor and ivacaftor are both substrates of CYP3A4; however, sensitivity to CYP3A4 metabolism was much greater for ivacaftor than lumacaftor. Neither lumacaftor nor ivacaftor is a substrate for OATP1B1 or OATP1B3 liver uptake transporters.

Based on studies in cultured human hepatocytes, lumacaftor has the potential to induce CYP3A4, CYP2B6, and the CYP2C family of enzymes; whereas ivacaftor, M1-ivacaftor, and M6-ivacaftor are not inducers of CYPs.

In *in vitro* inhibition studies, lumacaftor was a moderate inhibitor of CYP2C8 and ivacaftor has potential to inhibit CYP2C8 and CYP2C9, suggesting drug-drug interaction potential through inhibition of CYP2C8 and CYP2C9. Based on *in vitro* studies, lumacaftor and ivacaftor have potential to inhibit P-gp, but are not expected to inhibit OATP1B1 or OATP1B3.

Lumacaftor and ivacaftor were excreted predominately in the feces of all species evaluated. Lumacaftor was excreted primarily as the unchanged parent; whereas, ivacaftor was eliminated as polar oxidative metabolites. Lumacaftor and ivacaftor were also excreted in the milk of lactating rats.

**TOXICOLOGY**

The toxicities of lumacaftor and ivacaftor were evaluated in acute, repeat-dose, genetic, carcinogenicity, developmental and reproductive, local tolerance, and other toxicity studies.
Acute Toxicity

**Lumacaftor**

Lumacaftor demonstrated a low potential for acute toxicity from high single doses in both rats and mice (maximum tolerated dose [MTD] ≥2000 mg/kg for both species). The established MTDs represent 10- to 20-times the MRHD on a mg/kg basis (assuming a 50-kg human).

**Ivacaftor**

Ivacaftor demonstrated a low potential for acute toxicity from high single doses in both mice, (MTD=2000 mg/kg) and rats (MTD=500 mg/kg). No ivacaftor-related adverse effects were seen at levels that represent 8- to 16-times the MRHD on a mg/kg basis (assuming a 50-kg human).

Repeat-dose Toxicity

**Lumacaftor**

Repeat-dose toxicity studies in mice up to 3 months, rats up to 6 months, and dogs up to 12 months in duration failed to identify any target organs of lumacaftor-related toxicity at dose levels up to and exceeding the MTDs established in these species in the 3-month studies. Noteworthy findings observed in both rats and dogs following repeated administration were limited to dose-related body weight decrements and dose-related minimal-to-moderate decreases in erythrocytic parameters which were regenerative in rats and non-regenerative in dogs. Noteworthy findings observed only in rats following repeated administration included the regenerative response to decreases in erythrocytic parameters (comprising an increase in circulating reticulocytes and, at high doses, extramedullary hematopoiesis in the spleen); and microscopic findings of minimal centrilobular hypertrophy in male livers at high doses considered an adaptive or compensatory response to the observed cytochrome P450 (CYP) induction in rats. Noteworthy findings observed only in dogs following repeated administration included mortality (3 animals requiring euthanasia due to deteriorating body condition, severely decreased food consumption, and/or associated clinical signs) occurring at a dose level clearly exceeding the MTD in this species as evidenced by additional clinical signs of toxicity (irregular gait, trembling, jerky movements, and/or muscle rigidity) observed sporadically in individual animals combined with significant body weight decrements (23%) noted in both sexes. With exception of those adverse effects noted at dose levels exceeding the MTD in dogs, these noteworthy findings were considered non-adverse, did not progress in severity over time, and were reversible or partially-reversible following recovery assessments built into the respective study designs.

In the chronic toxicity studies, lumacaftor exposures at the no observed adverse effect level (NOAEL) in rats (1000 mg/kg/day) and dogs (500 mg/kg/day), were at least 1.1- to 8-fold higher than established steady-state AUC\(_{0-24hr}\) (396 mcg/hr/mL) at the recommended human therapeutic dose administered in combination with ivacaftor as ORKAMBI.

**Ivacaftor**

Ivacaftor was tested in repeat-dose studies of up to 3 months in duration in mice, 6 months in duration in rats, and 12 months in duration in dogs. The only target organ of toxicity identified for ivacaftor was the liver of mice and rats. Clinical chemistry and/or morphological evidence of hepatotoxicity were observed at high dosages in mice (≥600 mg/kg/day in a 3-month study) and
rats (≥200 mg/kg/day in the 3-month study and ≥100 mg/kg/day in the 6-month study). In mice, the main clinical pathology changes at the end of 3 months of dosing were elevated alanine aminotransferase (ALT), alkaline phosphatase (ALP), and serum electrolytes relative to the control group, and lower cholesterol and glucose, which were accompanied by minimal foci of hepatocellular necrosis in only a few of the animals. The main ivacaftor-related clinical pathology changes in rats (relative to the control group) included prolongation of prothrombin time (PT) and activated partial thromboplastin time (APTT); increases in ALT, gamma-glutamyltransferase (GGT), total protein, and blood urea nitrogen (BUN); serum electrolyte changes; and lower bicarbonate. Dose-related elevations in liver weights were accompanied by histopathological findings of centrilobular hepatocellular necrosis with acute/subacute inflammation in a few rats and mixed inflammatory cells occasionally seen in the liver. The hepatic enzyme elevations were typically less than 3-fold greater than normal.

Occasional instances of atrio-ventricular (AV) block occurred in dogs in repeat-dose studies. AV block is a well-documented background finding in this species. In addition, a slight increase in the incidence of supraventricular premature complex (SVPC) runs was observed in the chronic (12-month) study. The SVPC runs, which occurred in only 3 out of 40 dogs in this study, consisted of multiple events within a single electrocardiogram (ECG) recording at dosages ≥30 mg/kg/day and were reversible following a 28-day recovery period. All other ECG parameters were normal in all groups and the SVPC runs were not accompanied by morphological changes in the heart or changes in health status of these dogs.

In the chronic toxicity studies, summed exposures to ivacaftor and its metabolites at the NOAEL in rats (50 mg/kg/day) and dogs (60 mg/kg/day), were at least 3.6- to 6.4-fold higher than the established steady-state summed AUC0-24hr (81.12 mcg∙hr/mL) at the recommended human therapeutic dosage administered in combination with lumacaftor as ORKAMBI.

**Lumacaftor and Ivacaftor Combination**

A combination repeat-dose toxicity study involving the co-administration of lumacaftor and ivacaftor up to 3 months in duration in rats and 28 days in duration in dogs failed to produce any unexpected toxicities or interactions. Noteworthy findings in dogs were limited to a higher incidence of non-adverse cardiovascular findings (PR prolongation and AV block at doses ≥600/15 mg/kg/day lumacaftor/ivacaftor, and SVPC runs at doses of 600/60 mg/kg/day lumacaftor/ivacaftor) than previously noted in studies conducted with ivacaftor alone. Noteworthy findings in rats were limited to non-adverse microscopic findings of occasional small foci of erosion and necrosis in the glandular mucosa of the stomach, indicating that the combination was irritating to the gastrointestinal tract of rats (observed at doses ≥500/10 mg/kg/day lumacaftor/ivacaftor). These findings were not observed in dogs and were attributed to a local irritant effect of lumacaftor and ivacaftor at high concentrations that are likely not relevant to humans administered lumacaftor in combination with ivacaftor.

**Genotoxicity**

**Lumacaftor**

Lumacaftor was shown to be non-mutagenic and non-clastogenic in the following standard *in vitro* and *in vivo* genotoxicity tests: Ames test for bacterial gene mutation, *in vitro*
chromosomal aberration assay in Chinese hamster ovary cells, and in vivo mouse micronucleus test.

Ivacaftor
Ivacaftor was shown to be non-mutagenic and non-clastogenic in the following standard in vitro and in vivo genotoxicity tests: Ames test for bacterial gene mutation, in vitro chromosomal aberration assay in Chinese hamster ovary cells, and in vivo mouse micronucleus test.

Carcinogenicity
Lumacaftor
A two-year study conducted in rats and a 26-week study conducted in transgenic Tg.rasH2 mice to assess carcinogenic potential of lumacaftor demonstrated that lumacaftor was not carcinogenic. Plasma exposures in male and female rats at the non-carcinogenic dosage (1000 mg/kg/day, the highest dosage tested) were 5.4- to 12.7-fold higher than the plasma levels for the lumacaftor component of ORKAMBI measured in humans following combination therapy. Plasma exposures to lumacaftor in mice at the non-carcinogenic dosage (2000 and 1500 mg/kg/day, the highest dose tested for each sex) were approximately 3.5- to 5.3-fold higher than the plasma levels for the lumacaftor component of ORKAMBI measured in humans following combination therapy.

Ivacaftor
Two-year studies in mice and rats to assess carcinogenic potential of ivacaftor demonstrated that ivacaftor was not carcinogenic in either species. Summed plasma exposures to ivacaftor and metabolites in mice at the non-carcinogenic dosage (200 mg/kg/day, the highest dosage tested) were approximately 1.7- to 3.4-fold higher than the summed plasma levels for the ivacaftor and metabolites components of ORKAMBI measured in humans following combination therapy. Summed plasma exposures to ivacaftor and its metabolites in rats at the non-carcinogenic dosage (50 mg/kg/day, the highest dosage tested) were approximately 8.9- to 13-fold higher than the summed plasma levels for the ivacaftor and its metabolites components of ORKAMBI measured in humans following combination therapy.

Developmental and Reproductive Toxicity
Lumacaftor
Lumacaftor had no effects on fertility and reproductive performance indices in male and female rats at 1000 mg/kg/day (approximately 3 and 8 times, respectively, the MRHD for the lumacaftor component of ORKAMBI on a lumacaftor AUC basis extrapolated from lumacaftor exposures in the 6-month repeat-dose toxicity study in this species). Lumacaftor was not teratogenic in rats at approximately 8 times the MRHD of the lumacaftor component of ORKAMBI (on a lumacaftor AUC basis at a maternal dose of 2000 mg/kg/day). Lumacaftor was not teratogenic in rabbits at approximately 5 times the MRHD of the lumacaftor component of ORKAMBI (on a lumacaftor AUC basis at a maternal dose of 200 mg/kg/day). Placental transfer of lumacaftor was observed in pregnant rats and rabbits. Lumacaftor did not cause developmental defects (learning and memory, reproductive capacity) in the offspring of pregnant rats dosed orally from pregnancy through parturition and weaning.

Ivacaftor
Ivacaftor impaired fertility and reproductive performance indices in male and female rats at 200 mg/kg/day (approximately 11 and 7 times, respectively, the MRHD of the ivacaftor component of ORKAMBI based on summed AUCs of ivacaftor and its metabolites extrapolated from Day 90 exposures at 150 mg/kg/day in the 6-month repeat-dose toxicity study in males and Day 17 of the pilot embryofetal developmental study in this species). Decreased weight of seminal vesicles in males and increases in prolonged diestrus in females were observed at 200 mg/kg/day. Ivacaftor decreased the fertility index in female rats and the number of corpora lutea, implantations, and viable embryos at 200 mg/kg/day when dams were dosed prior to and during early pregnancy. No effects on male or female fertility and reproductive performance indices were observed at ≤100 mg/kg/day (approximately 8 and 4.5 times the MRHD based on summed AUCs of the ivacaftor component of ORKAMBI based on summed AUCs of ivacaftor and its metabolites extrapolated from Day 90 exposures at 100 mg/kg/day in the 6-month repeat-dose toxicity study in this species). Ivacaftor was not teratogenic in rats at approximately 7 times the MRHD of the ivacaftor component of ORKAMBI (based on summed AUCs for ivacaftor and its metabolites at a maternal dose of 200 mg/kg/day extrapolated from ivacaftor female exposures in the pilot embryofetal development study and female metabolite-to-parent ratios in the 6-month toxicity study in this species). Ivacaftor was not teratogenic in rabbits at approximately 46 times the MRHD of the ivacaftor component of ORKAMBI (on an ivacaftor AUC basis at a maternal dose of 100 mg/kg/day). Placental transfer of ivacaftor was observed in pregnant rats and rabbits. Ivacaftor did not cause developmental defects (learning and memory, reproductive capacity) in the offspring of pregnant rats dosed orally from pregnancy through parturition and weaning. M1 and M6 were not directly quantitated in the developmental and reproductive toxicity studies.

Cataracts were seen in juvenile rats dosed with ivacaftor from postnatal day 7 to 35 at dose levels of 10 mg/kg/day and higher (approximately 0.32 times the MRHD for the ivacaftor component of ORKAMBI based on summed AUCs of ivacaftor and metabolites). This finding was not observed in older animals.

Other Toxicity

**Lumacaftor**

Lumacaftor was determined to be non-irritating to skin based on results in the *in vitro* EPISKIN™ skin irritation test. Lumacaftor was classified as a non-irritant to eyes when tested *in vitro* on isolated bovine corneas (bovine corneal opacity and permeability assay). In a murine local lymph node assay, lumacaftor had no effects on the proliferative response of lymph node cells from the draining auricular lymph nodes, demonstrating that lumacaftor does not show the potential to induce skin sensitization.

**Ivacaftor**

Ivacaftor was not irritating to skin after topical administration to rabbits. Ivacaftor was classified as a non-irritant to eyes when tested *in vitro* on isolated bovine corneas (bovine corneal opacity and permeability assay). In a murine local lymph node assay, ivacaftor had no effects on the proliferative response of lymph node cells from the draining auricular lymph nodes, demonstrating that ivacaftor does not show the potential to induce skin sensitization.

READ THIS FOR SAFE AND EFFECTIVE USE OF YOUR MEDICINE
PATIENT MEDICATION INFORMATION

PrORKAMBI®
lumacaftor / ivacaftor tablets
lumacaftor / ivacaftor granules

Read this carefully before you start taking ORKAMBI and each time you get a refill. This leaflet is a summary and will not tell you everything about this drug. Talk to your healthcare professional about your medical condition and treatment and ask if there is any new information about ORKAMBI.

What is ORKAMBI used for?
• ORKAMBI is for the chronic treatment of cystic fibrosis (CF). It is used for patients aged 2 years and older who have two copies of the F508del mutation in the cystic fibrosis transmembrane conductance regulator (CFTR) gene (F508del/F508del).
• ORKAMBI should not be used in patients other than those who have two copies of the F508del mutation in their CFTR gene.

It is not known if ORKAMBI is safe and effective in children under 2 years of age.

How does ORKAMBI work?
• The CFTR gene provides instructions to your cells to make the CFTR protein. This protein helps take chloride ions in and out of the cells in many organs of your body.
• People with CF have a lower amount of the CFTR protein and/or reduced function of the CFTR protein.
• ORKAMBI has two ingredients:
  o Lumacaftor, a CFTR corrector, increases the amount of the CFTR proteins at the cell surface.
  o Ivacaftor, a CFTR potentiator, makes the CFTR protein at the cell surface work better.

What are the ingredients in ORKAMBI?
Medicinal ingredients: lumacaftor and ivacaftor

Non-medicinal ingredients:
Lumacaftor/ivacaftor tablets
Tablet core: cellulose, microcrystalline; croscarmellose sodium; hypromellose acetate succinate; magnesium stearate; povidone; and sodium lauryl sulfate.

Tablet film coat: carmine, FD&C Blue #1, FD&C Blue #2, polyethylene glycol, polyvinyl alcohol, talc, and titanium dioxide.

Printing ink: ammonium hydroxide, iron oxide black, propylene glycol, and shellac.
Non-medicinal ingredients in lumacaftor/ivacaftor granules
cellulose, microcrystalline; croscarmellose sodium; hypromellose acetate succinate; povidone; sodium lauryl sulfate.

**ORKAMBI comes in the following dosage forms:**
Tablet: 100 mg lumacaftor/125 mg ivacaftor
Tablet: 200 mg lumacaftor/125 mg ivacaftor
Granules: 100 mg lumacaftor/125 mg ivacaftor
Granules: 150 mg lumacaftor/188 mg ivacaftor

Do not use ORKAMBI if:
- You are hypersensitive (allergic) to this drug or to any ingredient in the formulation or component of the container.

To help avoid side effects and ensure proper use, talk to your healthcare professional before you take ORKAMBI. Talk about any health conditions or problems you may have, including if you:
- have liver disease. Taking ORKAMBI when you already have severe liver disease can cause serious life-threatening problems. Your doctor should closely monitor you and may adjust your dose of ORKAMBI.
- have had an organ transplant.
- have high blood pressure, a low heart rate, or other heart conditions.
- have kidney disease.
- are using birth control (hormonal contraceptives including oral, injectable, transdermal, or implantable forms). Hormonal contraceptives should not be used as a method of birth control when taking ORKAMBI.
- are pregnant or plan to become pregnant. It is not known if ORKAMBI will harm your unborn baby. You and your doctor should decide if you will take ORKAMBI while you are pregnant.
- are breastfeeding or planning to breastfeed. It is not known if ORKAMBI passes into your breast milk. You and your doctor should decide if you will take ORKAMBI while you are breastfeeding.

Other warnings you should know about:
**Cataracts**
Cloudiness of the eye lens (cataract) has been seen in some children and adolescents while taking ORKAMBI. Your doctor may perform an eye exam before you start taking ORKAMBI and during treatment with ORKAMBI to look for cataracts.

**Abnormal test results**
Abnormal blood tests of the liver have been seen in some people receiving ORKAMBI. Your doctor will order some blood tests to check your liver:
- before you take ORKAMBI,
- every 3 months of the first year while you are taking ORKAMBI, and
- every year while you are taking ORKAMBI.
If you have had abnormal blood tests of the liver in the past, your doctor may order blood tests to check your liver more often.

Tell your doctor right away if you have any of these symptoms, which may be a sign of liver problems:
- Pain or discomfort in the upper right stomach (abdominal) area
- Yellowing of your skin or the white part of your eyes
- Loss of appetite
- Nausea or vomiting
- Dark urine
- Confusion
- Pale stools

Menstrual Irregularities
Women taking ORKAMBI may have irregular or abnormal periods. They may also have more bleeding during their periods. This happened mainly in women taking hormonal birth control.

Children
ORKAMBI is not for use in children under the age of 2 years. It is not known if ORKAMBI is safe and effective in children under 2 years of age.

Respiratory
You may experience shortness of breath or tightness in your chest when you first start taking ORKAMBI, especially if you have poor lung function. Your doctor may monitor you more closely if you have poor lung function.

Blood Pressure and Heart Rate (number of heart beats per minute)
An increase in blood pressure has been seen in some patients treated with ORKAMBI. Your doctor may monitor your blood pressure periodically during treatment with ORKAMBI.

A decrease in heart rate has been seen in some patients treated with ORKAMBI.

Tell your doctor if you are taking medicines that affect your blood pressure or heart rate.

Driving and using machines
It is not known if ORKAMBI causes dizziness. You should know how you react to ORKAMBI before driving or using heavy machinery.

Tell your healthcare professional about all the medicines you take, including any drugs, vitamins, minerals, natural supplements, or alternative medicines.

The following may interact with ORKAMBI:
- Antifungal medicines (used for the treatment of fungal infections) such as ketoconazole, itraconazole, posaconazole, voriconazole, fluconazole
• Antibiotic medicines (used for the treatment of bacterial infections) such as clarithromycin, rifabutin, rifampicin, levofloxacin, erythromycin
• Anticonvulsant medicines (used for the treatment of epileptic seizures) such as phenobarbital, carbamazepine, phenytoin
• Ranitidine, a medication used to treat peptic ulcers and gastroesophageal reflux disease
• St. John’s wort (Hypericum perforatum), an herbal medicine
• Benzodiazepines (used for the treatment of anxiety, insomnia, agitation, etc.) such as midazolam, triazolam
• Antidepressants such as citalopram, escitalopram, sertraline
• Anti-allergics such as montelukast
• Anti-inflammatory medications such as ibuprofen
• Immunosuppressants (used after an organ transplantation) such as cyclosporine, everolimus, sirolimus, tacrolimus
• Cardiac glycosides (used for the treatment of mild to moderate congestive heart failure and an abnormal heart rhythm called atrial fibrillation) such as digoxin
• Anticoagulants (used to prevent blood clots from forming or growing larger in blood and blood vessels) such as warfarin
• Hormonal contraceptives (used to prevent pregnancy) such as oral, injectable, skin patches (transdermal), and implantable products. These should not be relied upon as an effective method of birth control when given with ORKAMBI.
• Glucocorticoids (used to treat inflammation) such as methylprednisolone, prednisone
• Proton pump inhibitors (used to treat acid reflux disease and ulcers) such as omeprazole, esomeprazole, lansoprazole

Know the medicines you take. Keep a list of them to show your doctor and pharmacist when you get a new medicine.

How to take ORKAMBI:
In order to get the right amount of medicine in your body, ORKAMBI should always be taken with a fat-containing food. Meals and snacks recommended in CF guidelines contain acceptable amounts of fat. Examples of fat-containing food: meals that have been prepared with butter or oils, meals that have eggs, nuts, whole-milk dairy products (such as whole-milk, cheese, and yogurt), or meats.
• Take ORKAMBI exactly as your doctor tells you to take it, even if you feel well.
• Check with your doctor if you are not sure about your dose.
• Do not change the dose or stop taking ORKAMBI without first talking to your doctor.
• Your doctor may need to adjust your dose if you have liver disease or if you are taking medications that may interact with ORKAMBI.

ORKAMBI Tablets (for patients aged 6 years and older): The usual dose is to give 2 tablets every 12 hours by mouth with fat-containing food (see below).
• Do not break, crush, or chew the tablet. Swallow the tablet whole.
• Each ORKAMBI box contains 4 cartons, a 4-week supply.
• Each carton contains 7 blister strips, one for each day. Each blister strip contains 4 tablets - 2 morning doses and 2 evening doses.
• You may cut along the dotted line to separate your doses from the blister strip.
• **Morning dose:** unpeel the paper backing from a blister strip. Do not push the tablet through the paper backing because the tablet could break. Remove 2 ORKAMBI tablets and swallow them whole with food that contains fat.
• **Evening dose:** 12 hours after your first dose, unpeel the paper backing from another blister strip to remove 2 ORKAMBI tablets and swallow them whole with food that contains fat.

**ORKAMBI Granules (for children aged 2 through 5 years and weighing less than 14 kg):**
Your doctor will prescribe the appropriate amount based on weight. The usual dose is to give 1 lumacaftor 100 mg/ivacaftor 125 mg packet of granules every 12 hours with fat-containing food.

**ORKAMBI Granules (for children aged 2 through 5 years and weighing 14 kg or greater):** Your doctor will prescribe the appropriate amount based on weight. The usual dose is to give 1 lumacaftor 150 mg/ivacaftor 188 mg packet of granules every 12 hours with fat-containing food.

**How to prepare the granules:**
• Each ORKAMBI box contains 4 individual wallets, a 4-week supply.
• There are 7 days of granules in each wallet. Each wallet contains 14 packets of granules – 7 morning doses and 7 evening doses.
• Use all 7 days’ doses before starting a new wallet.
• Each packet is for single use only.

**Morning dose:** Remove the first dose from the wallet.
• Hold the packet with cut line on top.
• Shake the packet gently to settle the granules to the bottom of the packet.
• Tear or cut packet completely open along cut line.
• Pour all of the granules in the packet into 5 mL (1 teaspoon) of soft food or liquid which should be at or below room temperature (5 to 25ºC) and mix until granules are dissolved.
• Some examples of soft foods or liquids include puréed fruits or vegetables, flavoured yogurt or pudding, applesauce, milk, or juice (except grapefruit).
• **After mixing, give within 1 hour. Make sure all medicine is taken. This is very important for it to work properly and be effective.**
• If mixed with food, ORKAMBI granules must not be stored for future use.
• **Evening dose:** This dose should be taken 12 hours after your **Morning dose.** Follow the same steps listed above under **Morning dose.**

**Usual dose:**
**Patients ages 2 through 5 years and less than 14 kg:** give 1 packet of 100 mg lumacaftor/125 mg ivacaftor granules (morning and evening) every 12 hours with fat-containing food.
Patients Aged 2 through 5 Years and greater than or equal to 14 kg: give 1 packet of 150 mg lumacaftor/188 mg ivacaftor granules (morning and evening) every 12 hours with fat-containing food.

Patients aged 6 through 11 years: give 2 tablets of the 100 mg lumacaftor/125 mg ivacaftor tablets every 12 hours (morning and evening) just before or just after eating fat-containing food.

Patients aged 12 years and over: give 2 tablets of the 200 mg lumacaftor/125 mg ivacaftor tablets every 12 hours (morning and evening) just before or just after eating fat-containing food.

Refilling your prescription:
Remember to get a new prescription from your doctor or a refill from your pharmacy before all your tablets are taken.

Overdose:
If you think you have taken too much ORKAMBI, contact your healthcare professional, hospital emergency department or regional Poison Control Centre immediately, even if there are no symptoms. If possible, have your medicine and this leaflet with you.

Missed Dose:
If you miss a dose of ORKAMBI and:
- **it is within 6 hours** of when you usually take it, take your dose of ORKAMBI as prescribed as soon as possible with fat-containing food.
- **it is more than 6 hours** after the time you usually take it, do **not** take the missed dose. Wait until it is time for your next dose and take it at the usual time.
- **Do not** take 2 doses at the same time to make up for your missed dose.

What are possible side effects from using ORKAMBI?
These are not all the possible side effects you may feel when taking ORKAMBI. If you experience any side effects not listed here, contact your healthcare professional.

Please also see Warnings and Precautions.

Like all medicines, this medicine can cause side effects, although not everybody gets them.
- shortness of breath and/or chest tightness
- increase in blood pressure
- decrease in heart rate
- upper respiratory tract infection (common cold), including sore throat, stuffy or runny nose
- gastrointestinal symptoms, including nausea, diarrhea, and gas
- rash
- fatigue
- flu or flu-like symptoms
- increase in muscle enzyme levels
- irregular, abnormal, or painful periods (menses) and increase in the amount of menstrual
Additional side effects in children
Side effects seen in children are similar to those seen in adults and adolescents. Additional common side effects seen in children include:

- stuffy or runny nose
- headache
- stomach pain
- increased cough and/or sputum
- sore throat
- pulmonary exacerbations

Worsening of liver function has been seen in patients with severe liver disease. The worsening of liver function can be serious or fatal. Talk to your doctor if you have been told you have liver disease, as your doctor may need to adjust the dose of ORKAMBI.

Reporting Side Effects

You can report any suspected side effects associated with the use of health products to Health Canada by:

- Visiting the Web page on Adverse Reaction Reporting (https://www.canada.ca/en/health-canada/services/drugs-health-products/medeffect-canada/adverse-reaction-reporting.html) for information on how to report online, by mail or by fax; or

Calling Toll-free at 1-866-234-2345.

NOTE: Contact your health professional if you need information about how to manage your side effects. The Canada Vigilance Program does not provide medical advice.

Storage:
Do not use this medicine after the expiry date that is stated on the package after EXP. The expiry date refers to the last day of that month.

Store at or below 30°C.

Keep out of reach and sight of children.

You may need to read this leaflet again. Please do not throw this away.

If you want more information about ORKAMBI:
- Talk to your healthcare professional.
- Find the full product monograph that is prepared for healthcare professionals and includes this Patient Medication Information by visiting the Health Canada website (https://www.canada.ca/en/health-canada.html); the manufacturer’s website (http://www.vrtx.com/canada); or by calling 1-877-634-8789.
